Motivation Objectives

General Objective

Objectives

Reconstruct groundwater flow, age and brine evolution during the Wisconsinian (-120 ka to present) glaciation with a 3D numerical model over the Canadian landscape.

Specific Objectives

- Process understanding
- Subglacial pressure evolution
- Portion of meltwater that recharged groundwater
- Groundwater flow patterns, brine and age distribution

Numerical Model Recharge and seepage dynamics Groundwater flow, Brine and Mean Age Evolution

HydroGeoSphere (Therrien and Sudicky)

- Control-volume finite-element multi-continuum fully-coupled variably-saturated, surface-subsurface flow model.
- Density-dependent groundwater flow with 1D hydromechanical coupling.
- Brine transport (advection-dispersion equation) with brine generation (1rst-order source term).

Numerical Model Recharge and seepage dynamics Groundwater flow, Brine and Mean Age Evolution

Summary

Table: Summary of the average infiltration and exfiltration rates for the subglacial and periglacial environments during the glacial cycle and the last interglacial period.

	Infiltration [m/yr]	Exfiltration [m/yr]
Subglacial environment	2.47×10^{-3}	2.03×10^{-3}
Periglacial environment	1.30×10 ⁻⁶	7.08×10^{-6}
Interglacial period	2.87×10^{-5}	3.25×10 ⁻⁶

Conclusions

- Simulation results show that the Wisconsinian glaciation had a profound impact on continental groundwater flow patters and geochemistry
- In the subglacial environment, meltwater infiltration into the subsurface dominates when the ice sheet is growing. Conversely, groundwater exfiltrates during ice sheet regression.
- Over the glacial period, the average subglacial infiltration rate into the subsurface ranges between 0 and 6 mm/yr with an average of 2.5 mm/yr. At LGM, ~20% of subglacial meltwater recharged.
- Permafrost evolution and distribution strongly influences groundwater circulation patterns.
- Pressure signatures at depth due to ice loading remain and is still recovering at present.
